pal eigenvectors so that $W = [v_1, \dots, v_k]$.

PCA through SVD

A point x is projected as: $z_i = \sum_{i=1}^n \alpha_i^{(i)} k(x_i, x)$

Autoencoders

We want to minimize $\frac{1}{n}\sum_{i=1}^{n}||x_i-\hat{x}_i||_2^2$. $\hat{x} = f_{dec}(f_{enc}(x, \theta_{enc}); \theta_{dec})$ Lin.activation func. & square loss => PCA

Statistical Perspective

Assume that data is generated iid. by some

p(x,y). We want to find $f: X \mapsto Y$ that minimizes the **population risk**. Opt. Predictor for the Squared Loss

f minimizing the population risk:

 $f^*(x) = \mathbb{E}[y \mid X = x] = \int y \cdot p(y \mid x) dy$

Estimate $\hat{p}(y \mid x)$ with MLE:

 $\theta^* = \operatorname{argmax} \hat{p}(y_1, ..., y_n \mid x_1, ..., x_n, \theta)$ = argmin $-\sum \log p(y_i \mid x, \theta)$

The MLE for linear regression is unbiased and has minimum variance among all unbiased estimators. However, it can overfit.

activation function: $\phi(x, w) = \phi(w^{\top}x)$

• Output the majority vote of labels

Neural Networks w are the weights and $\varphi : \mathbb{R} \to \mathbb{R}$ is a nonlinear

Ex. Conditional Linear Gaussian

 $\hat{p}(y \mid x, \theta) = \mathcal{N}(y; w^{\top}x, \sigma^2)$

 $\hat{w} = \operatorname{argmax} p(y|x, \theta) = \operatorname{argmin} \sum (y_i - w^{\top} x_i)^2$

Introduce bias to reduce variance. The small

weight assumption is a Gaussian prior $w_i \sim$

 $\mathcal{N}(0,\beta^2)$. The posterior distribution of w is

The optimal \hat{w} can be found using MLE:

Maximum a Posteriori Estimate

given by: $p(w \mid x, y) = \frac{p(w) \cdot p(y \mid x, w)}{p(y \mid x)}$

and likelihoods (= loss functions).

f minimizing the population risk:

 $\hat{w} = \operatorname{argmax}_{w} p(w \mid \bar{x}, \bar{y})$

Now we want to find the MAP for w:

 $= \underset{w}{\operatorname{argmin}}_{w} - \log \frac{p(w) \cdot p(y \mid x, w)}{p(y \mid x)}$ $= \underset{w}{\operatorname{argmin}}_{w} \frac{\sigma^{2}}{\beta^{2}} ||w||_{2}^{2} + \sum_{i=1}^{n} (y_{i} - w^{\top} x_{i})^{2}$

Statistical Models for Classification

 $f^*(x) = \operatorname{argmax}_{\hat{v}} p(\hat{v} \mid x)$

Regularization can be understood as MAP in-

ference, with different priors (= regularizers)

 $\mathcal{N}(0, \sigma^2)$ and $f(x) = w^{\top}x$:

MLE for feature distribution:

 $\mu_y = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_j = y} x_j$

Assume Gaussian noise $y = f(x) + \varepsilon$ with $\varepsilon \sim$ Where: $p(x_i | y) = \mathcal{N}(x_i; \hat{\mu}_{y,i}, \sigma_{y,i}^2)$

 $\mu_{y,i} = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_j = y} x_{j,i}$

$$\sigma_{y,i}^{2} = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_j = y} x_{j,i}$$

$$\sigma_{y,i}^{2} = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_j = y} (x_{j,i} - \hat{\mu}_{y,i})^2$$
ions are made by:
$$\sigma_{y,i}^{2} = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_j = y} (x_{j,i} - \hat{\mu}_{y,i})^2$$

Predictions are made by: $y = \operatorname{argmax} p(\hat{y} \mid x) = \operatorname{argmax} p(\hat{y}) \cdot \prod^{d} p(x_i \mid \hat{y})$ **M-Step**: compute MLE of $\theta^{(t)}$ as for GBC.

Equivalent to decision rule for bin. class.: $y = \operatorname{sgn}\left(\log \frac{p(Y=+1 \mid x)}{p(Y=-1 \mid x)}\right)$

Where f(x) is called the discriminant function. with Lloyd's heuristics. If the conditional independence assumption is **Soft-EM Algorithm** violated, the classifier can be overconfident.

Gaussian Bayes Classifier weights for each point $(w_i = \pi_i = p(Z = j))$: No independence assumption, model the features with a multivariant Gaussian $\mathcal{N}(x; \mu_{\nu}, \Sigma_{\nu})$:

 $\Sigma_{y} = \frac{1}{\text{Count}(Y=y)} \sum_{j \mid y_{j}=y} (x_{j} - \hat{\mu}_{y}) (x_{j} - \hat{\mu}_{y})^{\top}$ This is also called the quadratic discriminant analysis (QDA). LDA: $\Sigma_{+} = \Sigma_{-}$, Fisher LDA: This is called the Bayes' optimal predictor for $p(y) = \frac{1}{2}$, Outlier detection: $p(x) \le \tau$.

the 0-1 loss. Assuming iid. Bernoulli noise, the Avoiding Overfitting conditional probability is: MLE is prone to overfitting. Avoid this by $p(y \mid x, w) \sim \text{Ber}(y; \sigma(w^{\top}x))$ restricting model class (fewer parameters, e.g. Where $\sigma(z) = \frac{1}{1 + \exp(-z)}$ is the sigmoid function. GNB) or using priors (restrict param. values). Degeneracy of GMMs Generative vs. Discriminative Using MLE we get:

Discriminative models:

 $\hat{w} = \operatorname{argmin} \sum_{i=1}^{n} \log(1 + \exp(-y_i w^{\top} x_i))$ p(y|x), can't detect outliers, more robust **Generative models:** Which is the logistic loss. Instead of MLE we p(x,y), can be more powerful (dectect outliers, can estimate MĂP, e.g. with a Gaussian prior: missing values) if assumptions are met, are typically less robust against outliers

Gaussian Mixture Model Assume that data is generated from a convexcombination of Gaussian distributions:

 $p(x|\theta) = p(x|\mu, \Sigma, w) = \sum_{i=1}^{k} w_i \mathcal{N}(x; \mu_i, \Sigma_i)$ We don't have labels and want to cluster this **GMMs for Density Estimation** data. The problem is to estimate the param. for Can be used for anomaly detection or data imthe Gaussian distributions. $\operatorname{argmin}_{\theta} - \sum_{i=1}^{n} \log \sum_{i=1}^{k} w_{i} \cdot \mathcal{N}(x_{i} \mid \mu_{i}, \Sigma_{i})$ timated density against τ . Allows to control the

This is a non-convex objective. Similar to train-FP rate. Use ROC curve as evaluation criterion ing a GBC without labels. Start with guess for and optimize using CV to find τ . our parameters, predict the unknown labels and General EM Algorithm GM for classification tasks. Assuming for a then impute the missing data. Now we can get **E-Step**: Take the expected value over latent 1: $L(w) + \nabla L(w)^{\top}(v - w) \le L(v)$ class label, each feature is independent. This a closed form update. variables z to generate likelihood function Q: $Q(\theta; \theta^{(t-1)}) = \mathbb{E}_Z[\log p(X, Z \mid \theta) \mid X, \theta^{(t-1)}]$

 $\hat{w} = \operatorname{argmin} \lambda ||w||_2^2 + \sum_{i=1}^n \log(1 + e^{-y_i w^{\top} x_i})$ Bayesian Decision Theory

 $C: Y \times A \mapsto \mathbb{R}$, pick the action with the maximum expected utility. $a^* = \operatorname{argmin}_{a \in A} \mathbb{E}_{y}[C(y, a) \mid x]$

Given $p(y \mid x)$, a set of actions A and a cost

Can be used for asymetric costs or abstention.

Generative Modeling

Aim to estimate p(x,y) for complex situations using Bayes' rule: $p(x,y) = p(x|y) \cdot p(y)$ Naive Bayes Model

helps estimating $p(x \mid y) = \prod_{i=1}^{d} p(x_i \mid y_i)$. Gaussian Naive Bayes Classifier

Naive Bayes Model with Gaussians features. Estimate the parameters via MLE:

MLE for class prior: $p(y) = \hat{p}_y = \frac{\text{Count}(Y=y)}{...}$ **Hard-EM Algorithm** E-Step: predict the most likely class for each M-Step: Compute MLE / Maximize:

elled by a GMM.

 $p(x | y) = \sum_{i=1}^{k_y} w_i^{(y)} \mathcal{N}(x; \mu_i^{(y)}, \Sigma_i^{(y)})$

Giving highly complex decision boundaries:

 $p(y \mid x) = \frac{1}{z}p(y)\sum_{j=1}^{k_y} w_j^{(y)} \mathcal{N}(x; \mu_j^{(y)}, \Sigma_j^{(y)})$

 $z_{:}^{(t)} = \operatorname{argmax} p(z \mid x_i, \theta^{(t-1)})$

We have monotonic convergence, each EM-

with $\gamma_z(x) = p(z \mid x, \theta^{(t-1)})$

 $\theta^{(t)} = \operatorname{argmax} O(\theta; \theta^{(t-1)})$

Computing likelihood of the data becomes hard,

 $D_G(x) = \frac{p_{\rm data}(x)}{p_{\rm data}(x) + p_G(x)}$ The prob. of being fake is $1 - D_G$. Too

powerful discriminator could lead to memoriza-

tion of finite data. Other issues are oscilla-

 $DG = \max_{w'_D} M(w_G, w'_D) - \min_{w'_G} M(w'_G, w_D)$

 $\nabla_{x}x^{\top}A = A$ $\nabla_{x}a^{\top}x = \nabla_{x}x^{\top}a = a$

 $p(y \mid x) = \frac{1}{p(x)} \underbrace{p(y) \cdot p(x \mid y)}_{}$

Where $M(w_G, w_D)$ is the training objective.

 $+\mathbb{E}_{z\sim p_z}[\log(1-D(G(z,w_G),w_D))]$

therefore we need a different loss.

tions/divergence or mode collapse.

One possible performance metric:

= argmax $p(z \mid \theta^{(t-1)}) \cdot p(x_i \mid z, \theta^{(t-1)})$ iteration increases the data likelihood. **GANs** Learn f: "simple" distr. \mapsto non linear distr.

Problems: labels if the model is uncertain, tries to extract too much inf. Works poorly if clus-

 $\min \max \mathbb{E}_{x \sim p_{\text{data}}}[\log D(x, w_D)]$ ters are overlapping. With uniform weights and spherical covariances is equivalent to k-Means Training requires finding a saddle point, always converges to saddle point with if G, D have **E-Step**: calculate the cluster membership enough capacity. For a fixed G, the optimal dis-

 $\gamma_j^{(t)}(x_i) = p(Z = j \mid D) = \frac{w_j \cdot p(x_i; \theta_j^{(t-1)})}{\sum_k w_k \cdot p(x_i; \theta_k^{(t-1)})}$ M-Step: compute MLE with closed form:

 $w_j^{(t)} = \frac{1}{n} \sum_{i=1}^n \gamma_j^{(t)}(x_i) \qquad \mu_j^{(t)} = \frac{\sum_{i=1}^n x_i \cdot \gamma_j^{(t)}(x_i)}{\sum_{i=1}^n \gamma_i^{(t)}(x_i)}$ $\Sigma_{j}^{(t)} = \frac{\sum_{i=1}^{n} \gamma_{j}^{(t)}(x_{i})(x_{i} - \mu_{j}^{(t)})(x_{i} - \mu_{j}^{(t)})^{\top}}{\sum_{i=1}^{n} \gamma_{i}^{(t)}(x_{i})}$

Init. the weights as uniformly distributed, rand. or with k-Means++ and for variances use spherical init. or empirical covariance of the data. Various Select *k* using cross-validation.

GMMs can overfit with limited data. Avoid this $\nabla_x b^\top A x = A^\top b \quad \nabla_x x^\top x = 2x \quad \nabla_x x^\top A x = 2Ax$ $\nabla_w ||y - Xw||_2^2 = 2X^\top (Xw - y)$ by add v^2I to variance, so it does not collapse (equiv. to a Wishart prior on the covariance ma-**Bayes Theorem:** trix). Choose *v* by cross-validation. Gaussian-Mixture Bayes Classifiers Assume that $p(x \mid y)$ for each class can be mod-Normal Distribution:
